Abstract
The paper presents a software system, called ARCO, which enables museums to build virtual exhibitions of artifacts based on virtual and augmented reality technologies. The forms of virtual reality exhibitions can range from simple three-dimensional presentation of digitized objects, through interactive presentation of 3D spaces such as reconstructed interiors or architectural objects, to highly-interactive 3D educational games. With augmented reality it is possible to build exhibitions that present selected virtual objects in the context of real objects or real places, allowing a user to interact with virtual objects in a natural way. The ARCO system has been deployed in several museums with very promising initial results. Examples of virtual exhibitions built with the ARCO technology as well as their practical use in the museum context are presented in the paper.

Keywords
Virtual reality, augmented reality, 3D web, virtual museums, archaeology

1. Introduction

Archaeology is one of the applications which can benefit from the use of modern multimedia technologies such as virtual and augmented reality. Most museums do not have the space and the resources required to exhibit their whole collections. In addition, the nature and fragility of some of the objects prevent museum curators from making them available to the public. Also, interaction of museum visitors with the exhibited artifacts is usually very restricted, e.g., they cannot look at the artifacts from all angles, compare the artifacts, or study them in different contexts. In this respect, virtual and augmented reality technologies can offer great help. These technologies provide solutions enabling visualization of 3D digital models of museum artifacts in both purely virtual environments and mixed environments combining virtual objects and real objects. They also allow visitors to interact with the models in a variety of ways. Museums are keen on presenting their collections in a more appealing and exciting manner to attract visitors. Two main difficulties that museums encounter while trying to widely adopt virtual reality technologies in their standard way of operation are the efficient creation of 3D models of artifacts and building virtual exhibitions based on these models. Significant research effort has been recently undertaken in the area of 3D model creation. The technology becomes better, quicker and more affordable. It is expected that in the near future museums will be able to easily acquire high-quality 3D scanners. However, the availability of 3D models is a prerequisite but it is only the first step. For wider adoption of virtual museums technology, museums need efficient, cost-effective and simple methods of creating virtual and augmented reality exhibitions based on their collections of 3D models. The work of setting up an exhibition should be performed by museum staff (e.g., curators), who cannot be expected to be IT experts.

At the same time, the system must provide museum visitors with an intuitive human-computer interface based on well-known metaphors. The users should be able to interact with digital content easily and naturally, as they can interact with objects in the real world. Everything that does not meet these criteria will not be understood and, therefore, will not be generally accepted. The remainder of this paper is organized as follows. In Section 2 the state of the art in the domain of museum multimedia presentation systems is presented. Section 3 provides an overview of the ARCO system. Section 4 describes the process of designing virtual exhibitions in ARCO. Section 5 provides examples of virtual museum exhibitions built with ARCO. Section 6 discusses the use of ARCO in archaeological museums. Finally, Section 7 concludes the paper.
2. Current situation

Modern museums already exploit various multimedia technologies to attract visitors – both visitors coming to the museum in person and visitors on the internet. For the first type of visitors museums prepare on-site interfaces, such as kiosks, permitting them to browse through their digital collections and to access information related to the physical exhibitions. In most cases these interfaces are based on touch screen displays, while their content is programmed using popular technologies such as MS PowerPoint, PDF, HTML and Flash. Some museums invest in building custom interfaces (Wise 2002; Tyson 2003). For the second type of visitors museums prepare extensive websites describing the collections – often connected with virtual exhibitions of objects (British Museum 2008; Guggenheim Museum 2008). In most cases, these interfaces are based on either HTML or Flash technology and are mostly limited to 2D content. This form of presentation does not enable creation of fully-featured virtual exhibitions.

Museums are keen on presenting their collections in a more appealing and exciting manner. The most promising form of presenting virtual exhibitions is interactive 3D graphics. Museums are starting to apply 3D technologies in their interfaces accessible both inside the museums and on the web (Tsapatori et al. 2003). Most frequently, interactive photographs in the form of QuickTime VR are used, however true 3D standards, such as X3D and VRML, are also increasingly popular. In some cases, custom complex interfaces prepared with the use of 3D authoring tools such as 3ds max or Virtools (3ds max; Virtools) are used. The X3D/VRML standards are particularly interesting because they are not bound to any specific platform, enable presentation of content both inside the museum and over the internet. They also offer true 3D environments enabling the user to freely navigate in a 3D space and manipulate presented objects.

3. The ARCO system

The ARCO system – Augmented Representation of Cultural Objects – consist of a set of tools and technologies to help museums create, manipulate, manage and present digitized cultural objects in virtual exhibitions accessible both inside and outside museums (Walczak et al. 2006). The overall architecture of the ARCO system is presented in Fig. 1.
presentation allows users to search and browse the database contents through the use of a well-known interface, whereas the VR and AR exhibitions let them examine virtual reconstructions of selected objects in 3D environments. The virtual exhibitions displayed in the end-user interfaces are dynamically generated based on parameterized visualization templates and the database contents. The use of different visualization templates and template parameterization allows different visualizations of the same content. The virtual exhibitions can be also customized for a particular user or created in response to a user query.

4. Designing virtual exhibitions

The ARCO system uses the Flex-VR approach (Walczak 2008) based on dynamic modeling to create virtual exhibitions presented in the end-user interfaces. The dynamic modeling technique enables the development of dynamic database-driven virtual reality applications by building parameterized models (templates) of virtual scenes that constitute the application and dynamic generation of instances of virtual scenes based on the models, data retrieved from a database, current values of model parameters, query provided by a user, and user privileges or preferences (Walczak and Cellary 2002, 2003).

The use of presentation templates enables the separation of the process of designing complex virtual scenes from the process of creating actual virtual exhibitions, allowing the latter to be easily performed by museum staff without extensive knowledge in computer programming and 3D technologies. All the visualization rules necessary to build virtual exhibitions and most of the graphical properties of the exhibitions are encoded in the presentation templates. A content designer can create a virtual exhibition by simply collecting the cultural object models, setting their visualization properties and creating an instance of a presentation template, i.e. a template together with the values of template parameters (see Fig. 2). The process of designing a virtual exhibition can be performed by the use of a simple 2D application connected to the ARCO database.

The structure of virtual exhibitions is determined by the structure of exhibition spaces stored in the database. Each exhibition space may represent an entire exhibition, a part of the exhibition related to a particular subject, a museum room, etc. Subspaces may be used to divide exhibitions into smaller parts, e.g., focused on particular topics. The exhibition spaces are represented by folders, which may contain three types of elements:

- cultural objects,
- presentation template instances and
- cultural object selection rules.

When an end-user enters an exhibition space, all cultural objects that are assigned to this particular exhibition folder are displayed by the use of a presentation template instance that is assigned to this folder. A template instance is a template supplied with actual values for some of its formal parameters. The template parameter values are provided by a content designer by the use of the Presentation Manager tool (see Fig. 3).

Depending on the set of parameters that are set in the template instance, the end-user may be
required (or not) to provide parameters for displaying the exhibition contents. The following cases are possible:

- Some of the required template parameters are not set – the end-user must first provide values for these parameters (e.g., search criteria) and then the exhibition space may be visualized,
- All required parameters are set but there are optional parameters that are not set – the exhibition space is visualized immediately, but the end-user may change some of the presentation parameters (e.g., the default historical period),
- All template parameters are set – the exhibition space is displayed immediately and the end-user may not change its parameters.

This flexible assignment of parameter values to templates makes it possible to easily combine search interfaces, customizable browsing interfaces, as well as fixed virtual exhibitions. Due to the template parameterization, different visualizations can be achieved by the creation of template instances derived from the same template but supplied with different sets of parameter values. For example, a difference between two instances of the same template used in two spaces may be the value of a parameter defining the wall texture.

In order to speed-up the process of designing ARCO virtual exhibitions and to ensure consistency of presentation in exhibition spaces, the concept of inheritance of template instances was introduced. In this approach, if a specific exhibition folder does not contain its own template instance, the instance contained in its parent folder is used by default (recursively). This solution enables using one template instance for the whole tree of folders in the exhibition, saving the preparation time and ensuring visual consistency of presentations.

In the ARCO system, the same exhibition may be displayed differently in different environments by the use of different presentation templates. To achieve maximum flexibility with respect to different visualization methods, the concept of presentation domains was introduced. A presentation domain corresponds to the environment in which the presentation interface is used. Example presentation domains may be LOCAL, REMOTE and AR. The LOCAL domain is designed for use on local displays installed inside museum galleries. The REMOTE domain can be used on the internet. The content for local displays is optimized for full-screen use on fixed resolution touch-screen displays. The content must contain all navigation elements and the size of the elements must be appropriate for touch-screen operation. Since both the hardware and the network configuration are controlled by the museum, high-quality graphics can be employed within the local presentation domain. On the contrary, the REMOTE domain provides content for typical web presentations on computers with different hardware and software configurations connecting over the internet. The third domain: AR corresponds to Augmented Reality presentations used inside the museum. The list of presentation domains is extensible allowing museums to further differentiate the method of visualization in different contexts when necessary. Each presentation template is associated with a list of allowed presentation domains, but each template instance corresponds to a single domain. In an exhibition space, multiple instances of templates for different domains may be created, but one instance for each domain at most. While accessing a presentation, a user browser specifies which domain should be used. Then, the appropriate instance of the template is used to dynamically produce the content. This permits the creation of different visualizations of the same content for use in different environments, e.g. local web and remote web.

5. Example virtual exhibitions

Examples of ARCO interactive VR exhibition galleries are depicted in Figs 4 and 5.

Fig. 4 demonstrates a generic 3D gallery designed for presenting cultural objects in a virtual room. In this visualization, users can browse through objects simply by walking along the gallery and can retrieve more detailed information using interaction elements integrated into object stands. Fig. 5 illustrates a virtual exhibition of museum artifacts in a 3D room being a reconstruction of a real place – a corridor in the Victoria and Albert Museum in London (VAM 2008).

Using the Flex-VR approach it is possible to build more advanced interactive content. In Fig. 6, an example of a 3D interactive game is presented. The game lets users to learn about objects from the collections of the National Museum of Agriculture and Agricultural-Food Industry in Szreniawa (Szreniawa 2008). In this game, each of the cultural objects is associated with a scenario script, which governs its appearance and behavior in the virtual
scene. In this example, each object is represented by its geometrical model and a label indicating its material (retrieved from metadata). The user’s task is to associate each object with an appropriate label and then press the “Accept” button. From the content designer perspective, the creation of such scenarios requires only assigning a group of objects and a behavior template to an exhibition space. No programming or 3D designing skills are necessary.

In some circumstances, pure virtual environments may be insufficient, because they do not give the ability to see virtual objects in the context of real objects. This problem can be solved by the use of Augmented Reality visualization techniques that enable the visualization of virtual objects in real environments and interacting with the objects in a direct way.

In the ARCO system, AR visualization is possible by the use of a specially designed AR Application. The application overlays virtual objects upon a video stream captured by a camera, giving users an impression that the virtual objects actually exist in the real environment, and enabling the comparison of virtual and real objects. Users can indicate where the virtual objects should appear in the real scene using special physical markers. The markers take the form of square cardboard pieces with letters and special signs printed on their surfaces. A user can manipulate a marker in front of a camera as it is presented in Fig. 7 and look at an overlaid object from different angles and distances. To make navigation intuitive to users, the AR Application can also display standard 2D and 3D web content.

ARCO also enables building interactive AR scenarios, where, in addition to passive browsing, users can be involved in exercises, quizzes, games, etc. Interactive presentations can be composed of a number of different 3D models and other multimedia

6. ARCO in an Archaeological Museum

Implementation of the ARCO system in museums enables the creation of attractive low-cost exhibitions that otherwise would never be held. It is of remarkable importance for the promotion of cultural heritage, as well as of the country as a whole, particularly when it is faced with financial constraints. Of similar importance – especially for the younger generation of museum visitors – is the possibility to transform, thanks to the ARCO technology, the image of the museum itself: from a place where one can only passively watch cultural objects placed in closed show-cases, to a place where the original artifacts are accompanied by interactive, virtual exhibitions, of potentially unlimited scope, that enrich the main traditional exhibition. One can presume that the access to such presentations from home as well as from school through the internet (and, in the future, through the interactive digital television) on a worldwide scale, will exert a significant impact upon education of the young generations. Such a powerful and flexible system as ARCO enables archaeologists to generate several different types of products, i.e.:

1) Internet 3D presentations of traditional museum exhibitions (mainly the permanent ones);
2) Additional presentations of sets of artifacts that enrich traditional exhibitions
   a/ locally – at the museum (e.g., info kiosks),
   b/ remotely – through the internet;
3) Monographic (problem-oriented) exhibitions (artifacts and their multimedia descriptions based upon the contents of the ARCO database);
4) Educational programs for young people (e.g., educational games), accompanied by tests that check the newly acquired knowledge;
5) Artifact catalogues for professionals.

7. Conclusions

The ARCO system demonstrates that modern IT technologies, such as virtual and augmented reality, can provide museums with new, appealing means of presenting their collections. Based on these technologies museums can build interactive multimedia exhibitions, which can be very attractive to visitors. The exhibitions can be accessible either locally in the museums or remotely over the internet. Local exhibitions may be used to provide visitors with additional information about objects exhibited in the traditional way or to access digitized versions...
of objects that due to various reasons cannot be exhibited in the traditional way. Remote exhibitions may be used to increase public awareness and interest in the museum and to provide information for researchers and learning content for all kinds of educational institutions.
